

Geologic Map of the Monroe 7.5-minute Quadrangle, King and Snohomish Counties, Washington

by Joe D. Dragovich, Megan L. Anderson, Shannon A. Mahan, Curtis J. Koger, Jennifer H. Saltonstall, James H. MacDonald Jr., Gregory R. Wessel, Bruce A. Stoker, John P. Bethel, Julia E. Labadie, Recep Cakir, Jeffrey D. Bowman, and S. Andrew DuFranc

November 2011

MAJOR FINDINGS

- The Rattlesnake Mountain fault zone (RMFZ) is the southwest extension of the southern Whidbey Island fault zone (SWIF), and the Cherry Valley fault of the SWIF forms the northeastern boundary of the Seattle Basin in the map area.
- Snoqualmie and Skykomish River alluvium is similar to sands in the Pleistocene nonglacial deposits (ancient alluvium) that commonly exhibit moderate to intense liquefaction.
- Ancient alluvium is preserved in structural basins, some inverted, between active faults or as elevated tilted beds.
- The volcanic rocks of Mount Persis in the study area emanated from volcanic center(s) near the eastern edge of the map area.
- Offset along the Monroe fault may be actively uplifting the uplands between High Rock on the north and Cherry Creek on the south.
- The 1996 Duvall earthquake epicenters (max. magnitude 5.3) coincide with the mapped trace of the Cherry Creek fault zone (CCFZ), suggesting that these seismic events may have resulted from shallow displacement along this fault zone.

DESCRIPTION OF MAP UNITS (see pamphlet for detailed map unit descriptions)

Quaternary Sedimentary Deposits

HOLOCENE NONGLACIAL DEPOSITS

- Artificial fill and modified land (Holocene)**—Mixed earth materials including sand and gravel fill.
- Peat (Holocene)**—Peat, muck, and organic silt and clay, with local thin beds of lapilli.
- Alluvium (Holocene)**—Sand, silt, (cobble) gravel, gravelly sand, sandy pebble gravel, peat, and organic sediments, locally divided into:
 - Levee deposits (Holocene)**—Wedge-shaped accumulations of overbank flood sediments along the Snoqualmie and Skykomish Rivers.
 - Older Alluvium (Holocene to latest Pleistocene)**—Cobble to pebble gravel, sand, and silt forming elevated terraces along the margins of the Skykomish valley.
 - Landslide deposits (Holocene to latest Pleistocene)**—Diamiction or boulder gravel and local minor sand or gravel.
 - Alluvial fan deposits (Holocene to latest Pleistocene)**—Debris-flow diamiction and alluvial deposits.

PLEISTOCENE GLACIAL AND NONGLACIAL DEPOSITS

Recessional Deposits of the Vashon Stage of the Fraser Glaciation

- Recessional glaciolacustrine deposits**—Soft silt, clayey or sandy silt, and silty sand, typically with scattered dropstones, deposited in glacial lakes.
- Outwash sand**—Sand and pebbly sand, dark blue-gray; loose or soft; nonbedded to weakly stratified to plane bedded, laminated, and crossbedded.
- Deltaic outwash and kame deltas**—Cobble gravel to pebbly sand; loose; moderately to well sorted, thin to very thickly bedded and well stratified.
- Fluvial outwash deposits**—Bouldery cobble gravel to sand; loose; moderately to well stratified, subhorizontal beds, local crossbedding, and rip-up clasts.
- Ice-contact deposits, undivided**—Loose bouldery cobble gravel with lesser diamiction, sand (pebbly) sand, and silt; moderately stratified and medium to very thickly bedded; variably sorted with abrupt grain-size changes common. Locally divided into:
 - Ice-contact kames**—Sand and gravel with scattered lenses of diamiction; may include some kame delta deposits.
- Outwash gravel deposits, undivided**—Poorly exposed bouldery gravel to pebbly sand; loose; massive to crudely bedded, deposited mostly as ice-contact deposits, including kame outwash bodies.

Advance Proglacial and Subglacial Deposits of the Vashon Stage of the Fraser Glaciation

- Vashon lodgment till**—Diamiction; grayish blue to very dark gray; dense; matrix-supported; unsorted with cobbles and boulders in a silt-sand matrix.
- Vashon advance outwash**—Sand and gravel; dark green-gray; dense; well sorted and stratified, thinly to thickly bedded, local silt interbeds and (or) rip-up clasts, deltaic and bar foreset beds, cut-and-fill structures.
- Vashon advance glaciolacustrine deposits**—Silt and diamiction; contains scattered dropstones and iceberg melt-out till or flow till; stiff or dense; stratification and sorting variable.

Deposits of the Olympia Nonglacial Interval

- Olympia beds, Snoqualmie and Skykomish River provenance**—Sand and silt, with some clay, peat, and (cobble) gravel interbeds; yellowish brown-gray to grayish brown with distinctive orange-gray oxidation; dense; laminated to very thickly bedded and well stratified with liquefaction features common. Locally divided into:
 - Olympia beds, local provenance**—Silt, sand, and gravel, with peat and paleosols; dense; thickly to thinly bedded and well stratified and sorted.

Deposits of the Possession Glaciation

- Glaciomarine and glaciolacustrine deposits**—Silt and clay with scattered gravel dropstones; hard or dense; moderately to well sorted and typically massive or moderately stratified; laminations common.

Whidbey Formation

- Whidbey Formation, Snoqualmie and Skykomish River provenance**—Sand and silt with some clay, peat, and (cobble) gravel interbeds; yellow-gray or brown, weathering to orange-gray; dense or hard, well sorted and stratified; laminated to thickly bedded; commonly plane bedded; may contain evidence of liquefaction.

Deposits of the Double Bluff Glaciation

- Double Bluff till**—Dominantly diamiction; very dense and massive; basaltic clasts have distinct 1 to 2 mm weathering rinds.

Deposits of the Hamm Creek Formation of Troost and others (2005)

- Hamm Creek formation, Snoqualmie and Skykomish River provenance**—Sand and silt with clay, peat, and gravel interbeds; weathered to distinctive orange-brown; dense or hard, well sorted and stratified; laminated to thinly bedded; beds are disrupted from liquefaction.

PRE-FRASER GLACIAL AND NONGLACIAL DEPOSITS

- Pre-Fraser continental nonglacial deposits, Snoqualmie and Skykomish River provenance (Pleistocene)**—Sand and silt with clay, peat, and gravel interbeds; locally, yellow-brown-gray, weathering to orange-gray or light yellowish brown; dense; laminated to thickly bedded and well stratified; may contain trough and ripple crossbedding, graded beds and liquefaction features.
- Pre-Fraser glacial and nonglacial deposits, undivided (Pleistocene to Pliocene)(cross sections only)**—Mostly (boulder) gravel, sand and gravel, sand, silt, clay, diamiction, and some wood or peat; dense to very dense.

Tertiary Volcanic and Sedimentary Rocks

- Volcanic and sedimentary rocks (Miocene)(cross sections only)**—Nonmarine volcanic to tuffaceous sandstone, pebbly sandstone, volcanic to polyimic conglomerate, tuff, claystone, siltstone, and lignite; locally contains volcanic breccia.
- Blakeley Formation, nearshore marine deposits (Oligocene to latest Eocene)(cross sections only)**—Feldspathic to lithic (tuffaceous) sandstone, conglomerate, and tuff; well stratified, and laminated to thickly bedded.
- Blakeley Formation, fluvial-deltaic deposits (Oligocene to latest Eocene)(cross sections only)**—Lithic to lithic volcanic sandstone, pebbly sandstone, tuffaceous siltstone, claystone, tuff, lapilli tuff, conglomerate and rare coal, well stratified, and laminated to thickly bedded.
- Volcanic rocks of Mount Persis of Tabor and others (1993), undivided (Eocene)**—Volcanic lithic (tuffaceous) sandstone, tuffaceous siltstone, lahars and volcanic (boulder) conglomerate, andesitic flows, tuff breccia, and tuff, with minor silty shale, claystone, and coal; vary from andesite to basaltic andesite with some dacite and basalt, locally strongly altered, particularly near tectonic zones (units tz or tz+).

Volcanic rocks of Mount Persis, andesitic flows (Eocene)

- Andesitic flows and rare flow breccia, greenish gray, dark green, or dark gray, weathers to dark reddish brown-gray or yellow-brown-gray.

Volcanic rocks of Mount Persis, dark basaltic andesite flows (Eocene)

- Medium-K, calc-alkaline basaltic andesite to andesitic flows; typically dark gray to very dark gray, weathers to reddish gray.

Volcanic rocks of Mount Persis, basalt flows (Eocene)

- Calc-alkaline basalt, massive and dark gray.

Volcanic rocks of Mount Persis, tuffs (Eocene)

- Medium-K, calc-alkaline dacite to rhyolitic tuffs; light to dark gray to light yellowish brown, massive.

Volcanic rocks of Mount Persis, cream-colored lapilli tuffs (Eocene)

- Medium-K, calc-alkaline dacite lapilli tuffs, locally with some tuff breccia, typically pale brown, weathering to cream, pumice clasts are white and lithic clasts vary from green to gray.

Volcanic rocks of Mount Persis, dark tuffs (Eocene)

- Medium-K, calc-alkaline dacite to rhyolitic crystal viric and vitric tuffs; typically dark gray, weathering to brown.

Volcanic rocks of Mount Persis, volcanic breccia (Eocene)

- Andesitic to dacitic lithic, tuff breccia and lapilli tuff, multicolored but generally dark green-gray to gray, weathering to brown.

Volcanic rocks of Mount Persis, volcanic bomb breccia (Eocene)

- Medium-K, calc-alkaline dacite lithic bomb breccia; typically with reddish gray or dark gray clasts.

Volcanic rocks of Mount Persis, volcanoclastic rocks (Eocene)

- Lithic and feldspathic volcanic to tuffaceous sandstone, siltstone, and volcanic conglomerate; color variable but mostly light yellowish brown to very pale brown to light bluish gray; mostly well sorted and stratified.

Volcanic rocks of Mount Persis, lahars (Eocene)

- Colloidal to noncolloidal lahar and volcanic boulder conglomerate; clasts dark gray, commonly weathered or altered to gray-green, contains subrounded to subangular pebbles to boulders of andesite.

Volcanic rocks of Mount Persis, intrusive complex (Eocene)

- Uniquely textured medium-K calc-alkaline dacite or andesite flows, monochrome lapilli tuff, and dacitic bomb breccia; bluish gray to gray.

Paget Group, undivided (Eocene)(cross sections only)

- Mostly continental feldspathic to volcanic lithic subaqueous sandstone, siltstone, claystone, lapilli tuff, and tuff and lesser carbonaceous shale, pebble conglomerate, and coal.

Mesozoic Low-Grade Metamorphic Rocks (Pheinite-Pumpellyite Facies)

- Western mélange belt of Tabor and others (1993)(Cretaceous to Jurassic) (cross sections only)**—Metamorphosed argillite, sandstone, greenstone, gabbro, and diabase with minor metachert, metasilica, silt, phyllite, marble, and rare ultramafite.

Tertiary to Holocene Tectonic Zones

- Tectonic zone (Tertiary to Holocene)**—Cataclastic, fault breccia, clay-rich fault gouge, protomylonite, and strongly slickensided and fractured rocks in fault zones; variously colored, mottled, and veined as a result of local hydrothermal alteration or strong weathering; low-temperature, hydrothermally altered zones (unit tz) produce a whitish rock. **Quaternary tectonic zones** (unit Qz) are areas of probable Quaternary deformation shown only on the cross sections.

Geologic Symbols

- Contact**—Solid where location accurate; dashed where inferred, queried where identity or existence questionable.
- Fault, unknown offset**—Solid where location accurate; dashed where inferred, dotted where concealed, queried where identity or existence questionable.
- Reverse fault**—Solid where location accurate; dashed where inferred, dotted where concealed, queried where identity or existence questionable; rectangles on upthrown block.
- Thrust fault**—Solid where location accurate, dotted where concealed, sawtooth on upper plate.
- Right-lateral strike-slip fault**—Solid where location accurate; dashed where inferred, dotted where concealed, queried where identity or existence questionable; arrows show relative motion.
- Left-lateral strike-slip fault**—Solid where location accurate; dashed where inferred, dotted where concealed, queried where identity or existence questionable; arrows show relative motion.
- Reverse left-lateral oblique-slip fault**—Solid where location accurate; dashed where inferred, dotted where concealed, queried where identity or existence questionable; rectangles on upthrown block.
- High-angle right-lateral, oblique-slip fault**—Location concealed; queried where identity or existence questionable; arrows show relative horizontal motion, U, upthrown block; D, downthrown block.
- High-angle left-lateral, oblique-slip fault**—Solid where location accurate; dashed where inferred, dotted where concealed, queried where identity or existence questionable; U, upthrown block; D, downthrown block.
- Anticline**—Solid where location accurate; dashed where approximate, dotted where concealed, queried where identity or existence questionable.

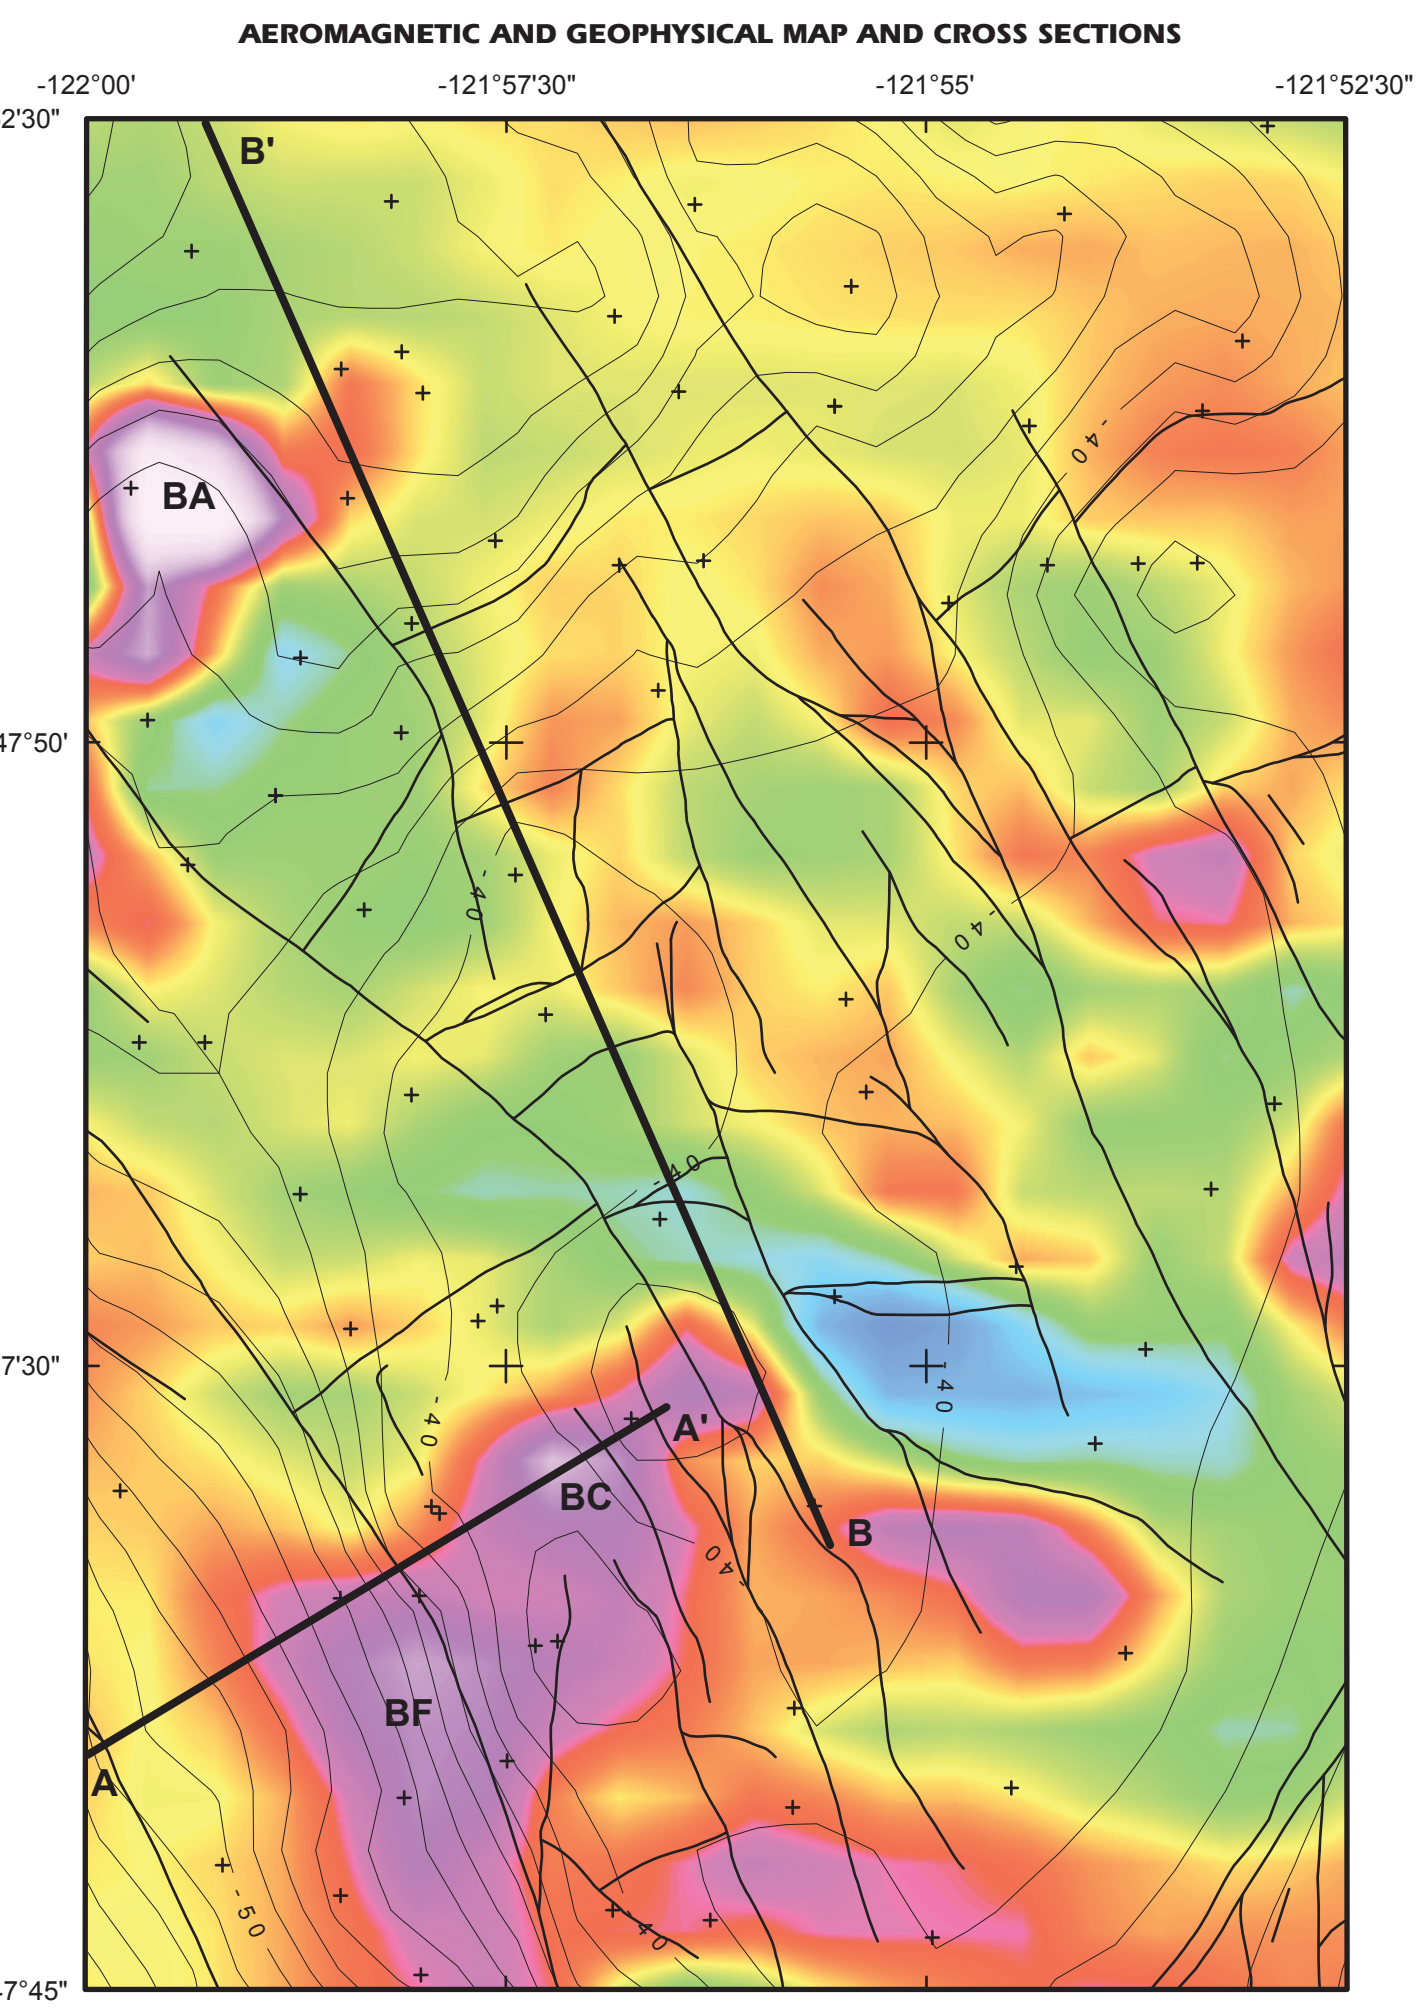

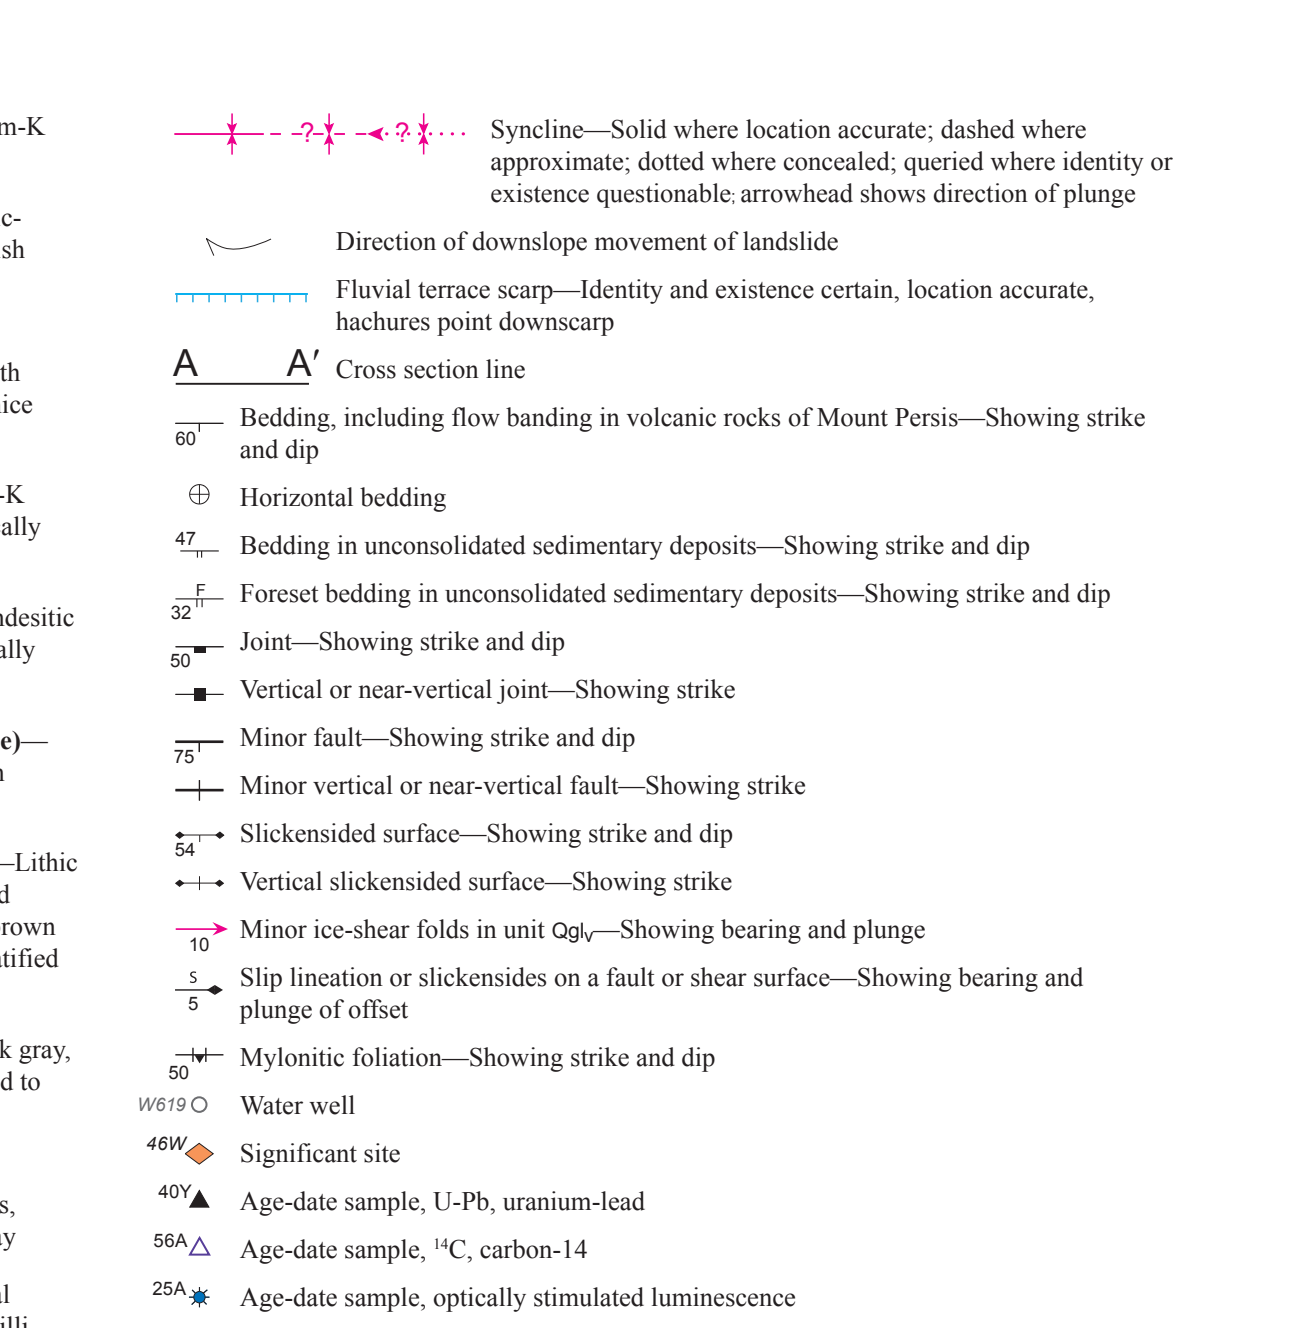

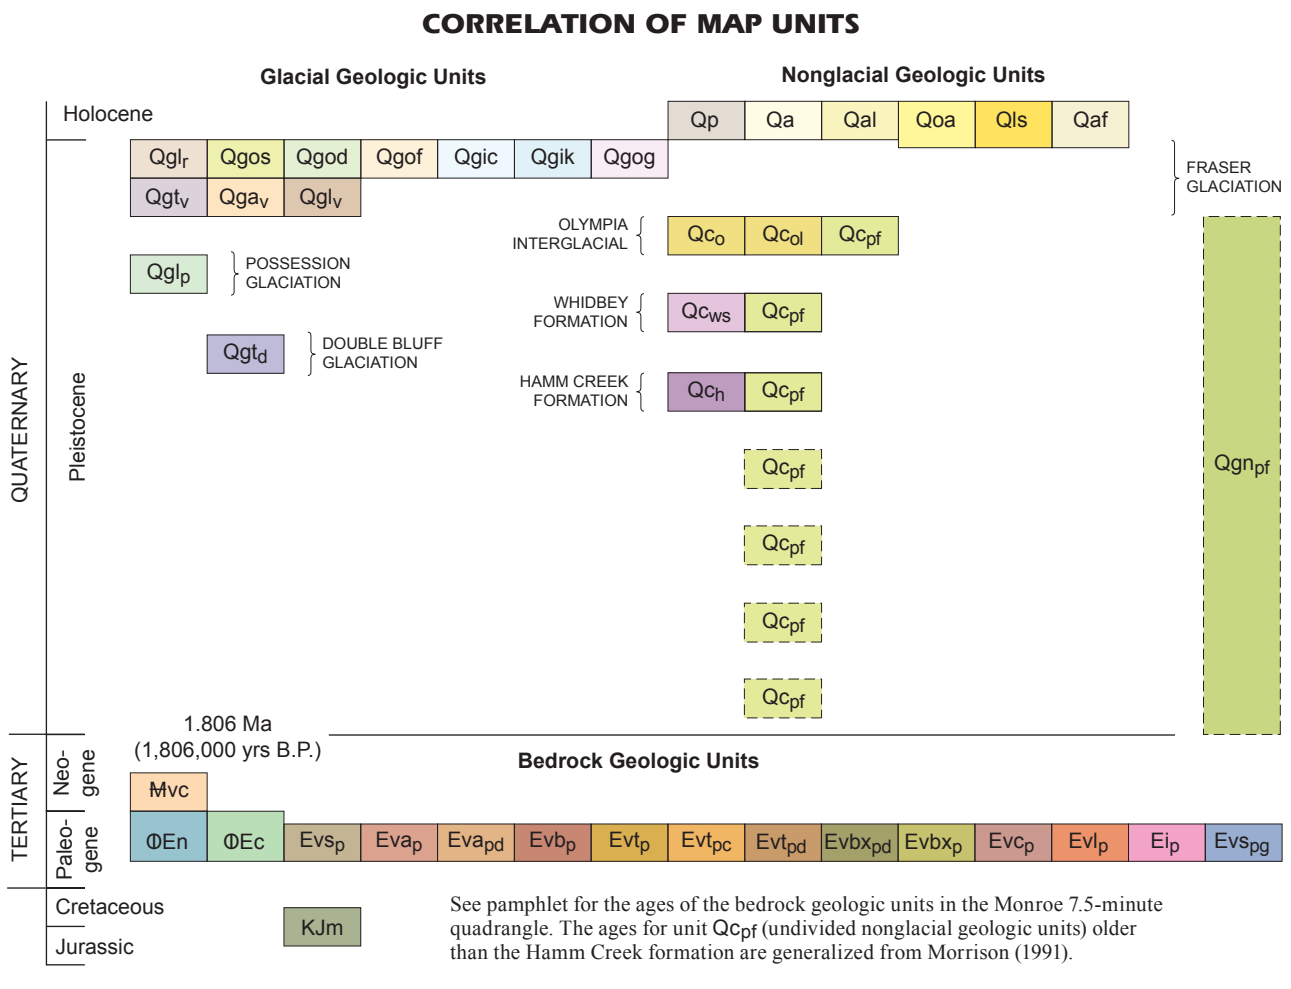

Figure 1. Aeromagnetic and gravity geophysical map of the Monroe quadrangle. Base map is the reduced-to-pole aeromagnetic anomaly map, filtered (upward continued and differenced with original grid) to bring out near-surface magnetic anomalies. Isostatic gravity contours (1 mGal interval) are labeled in mGal. Darker lines are faults from the geologic map. Crosses indicate location of gravity measurements controlling the isostatic gravity grid. BA, basalt outcrop; BF, basalt flows buried on the edge of the Seattle basin; BC, interpreted channelized basalts.

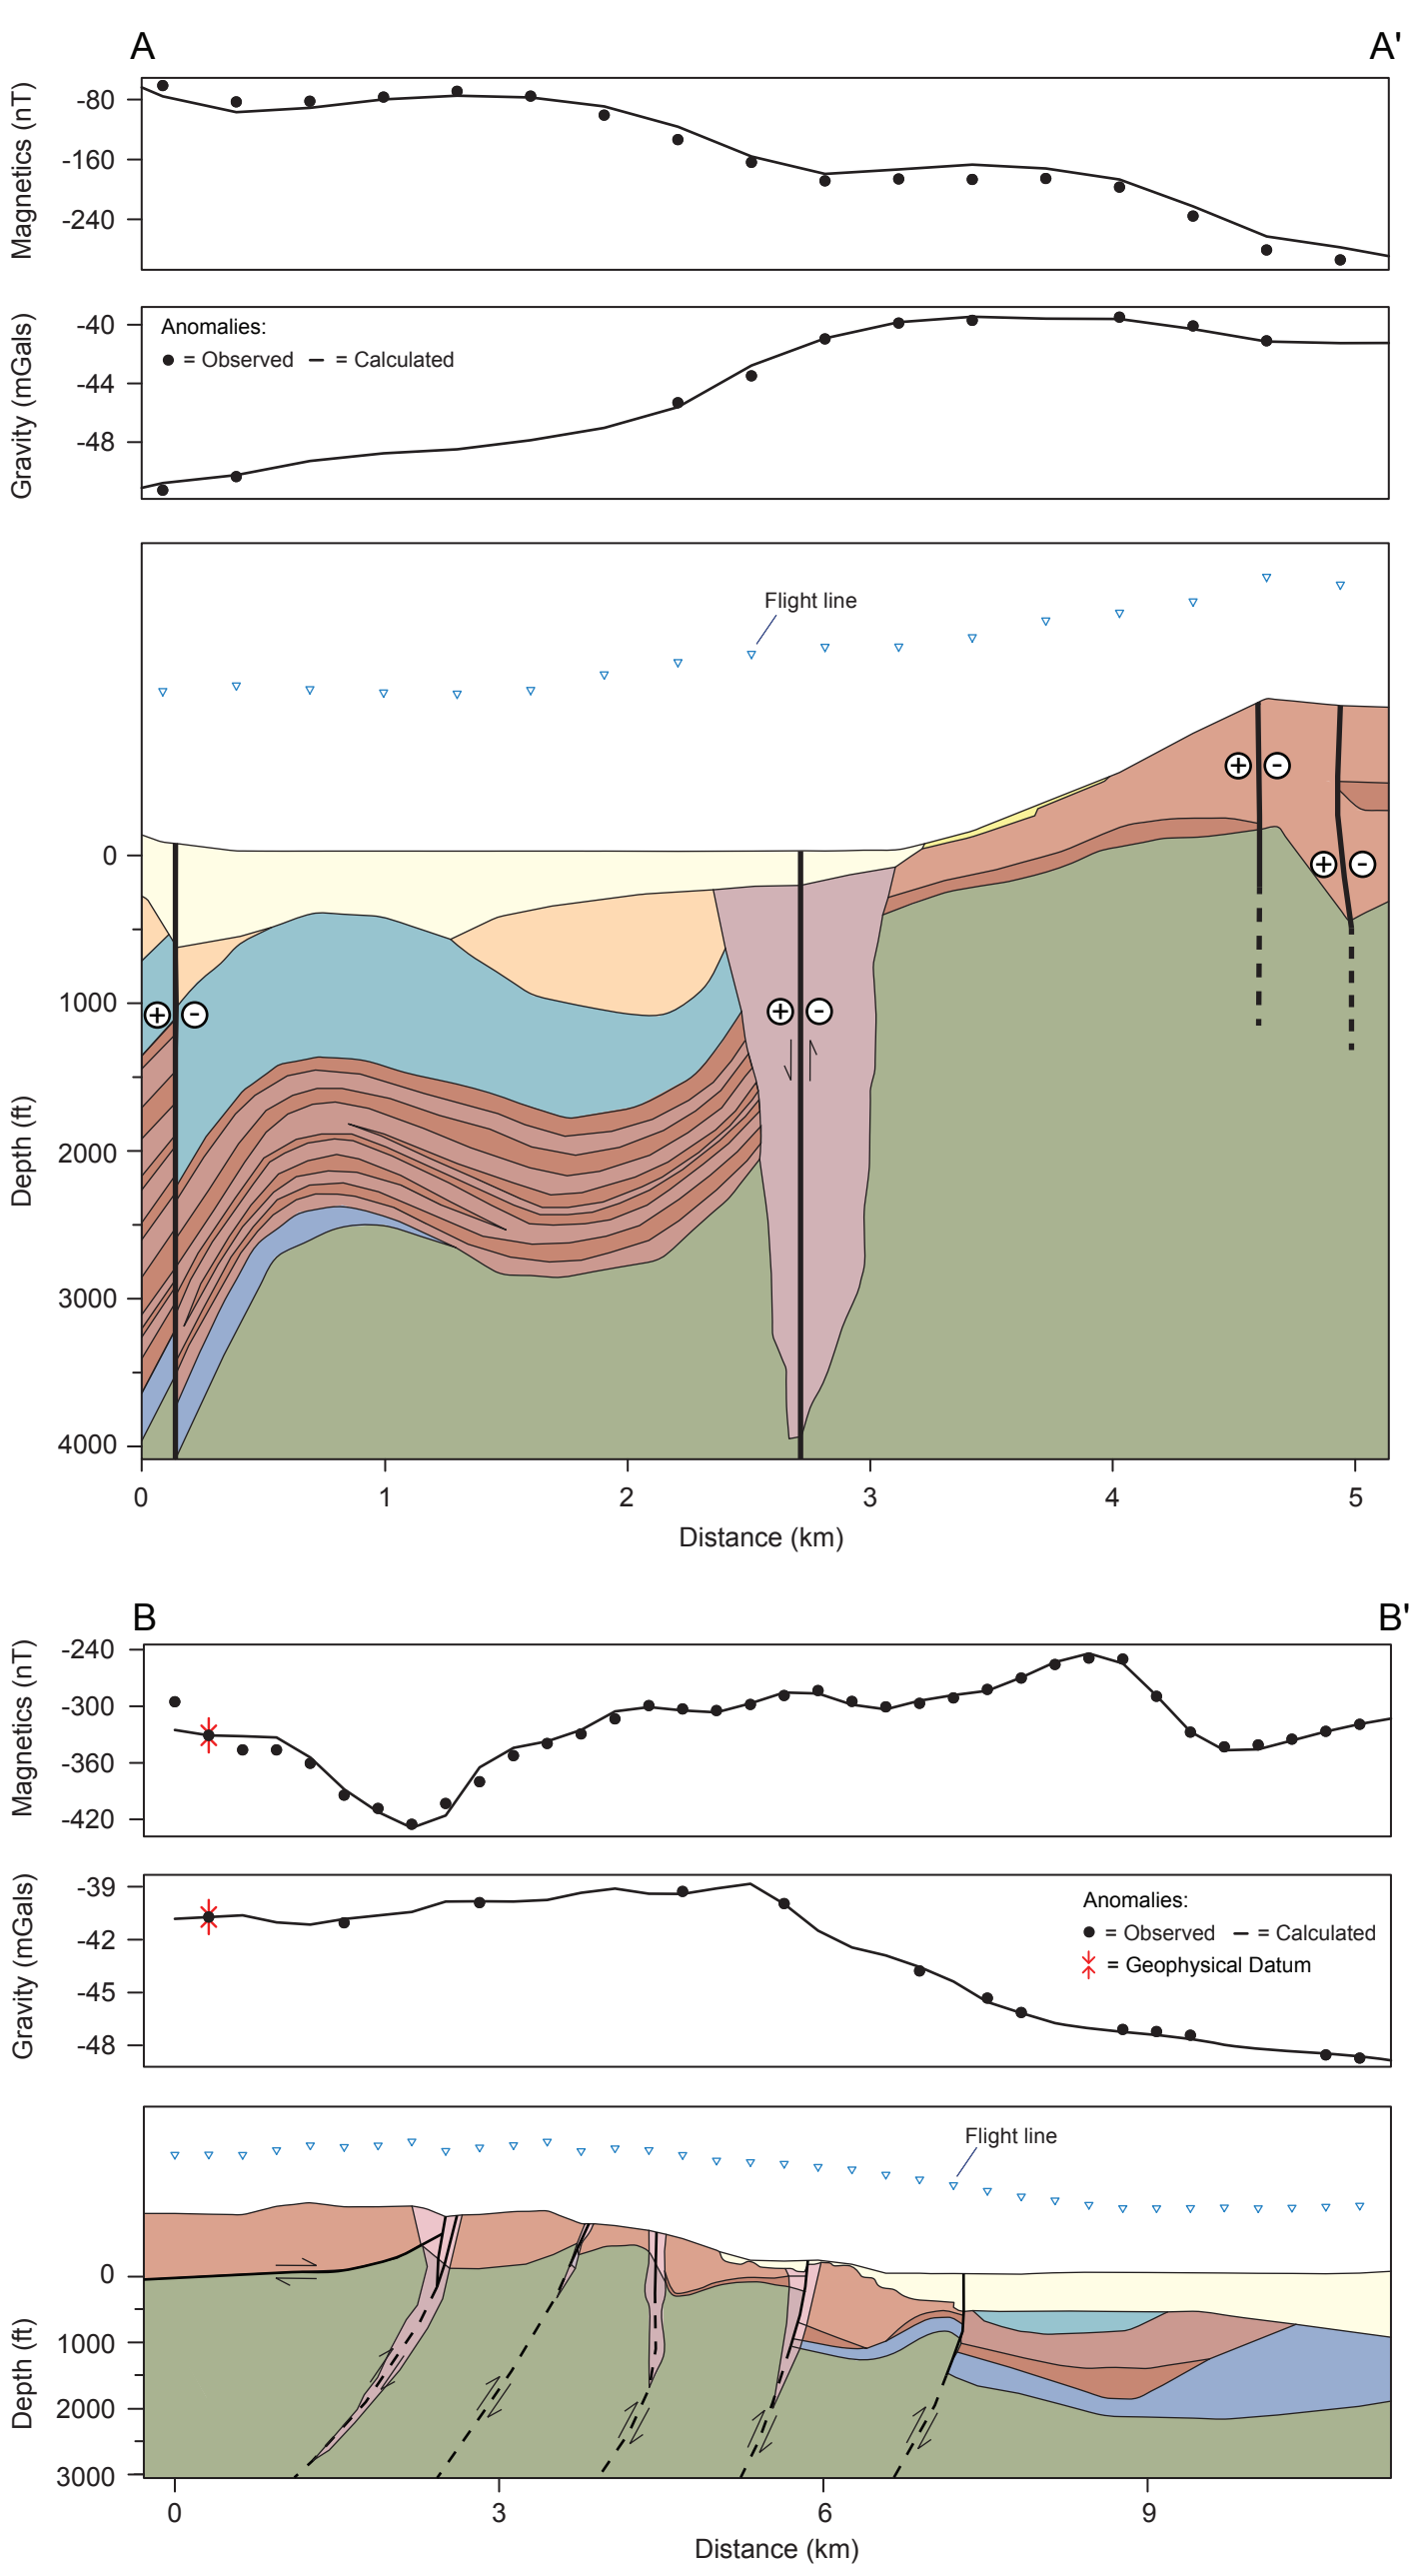

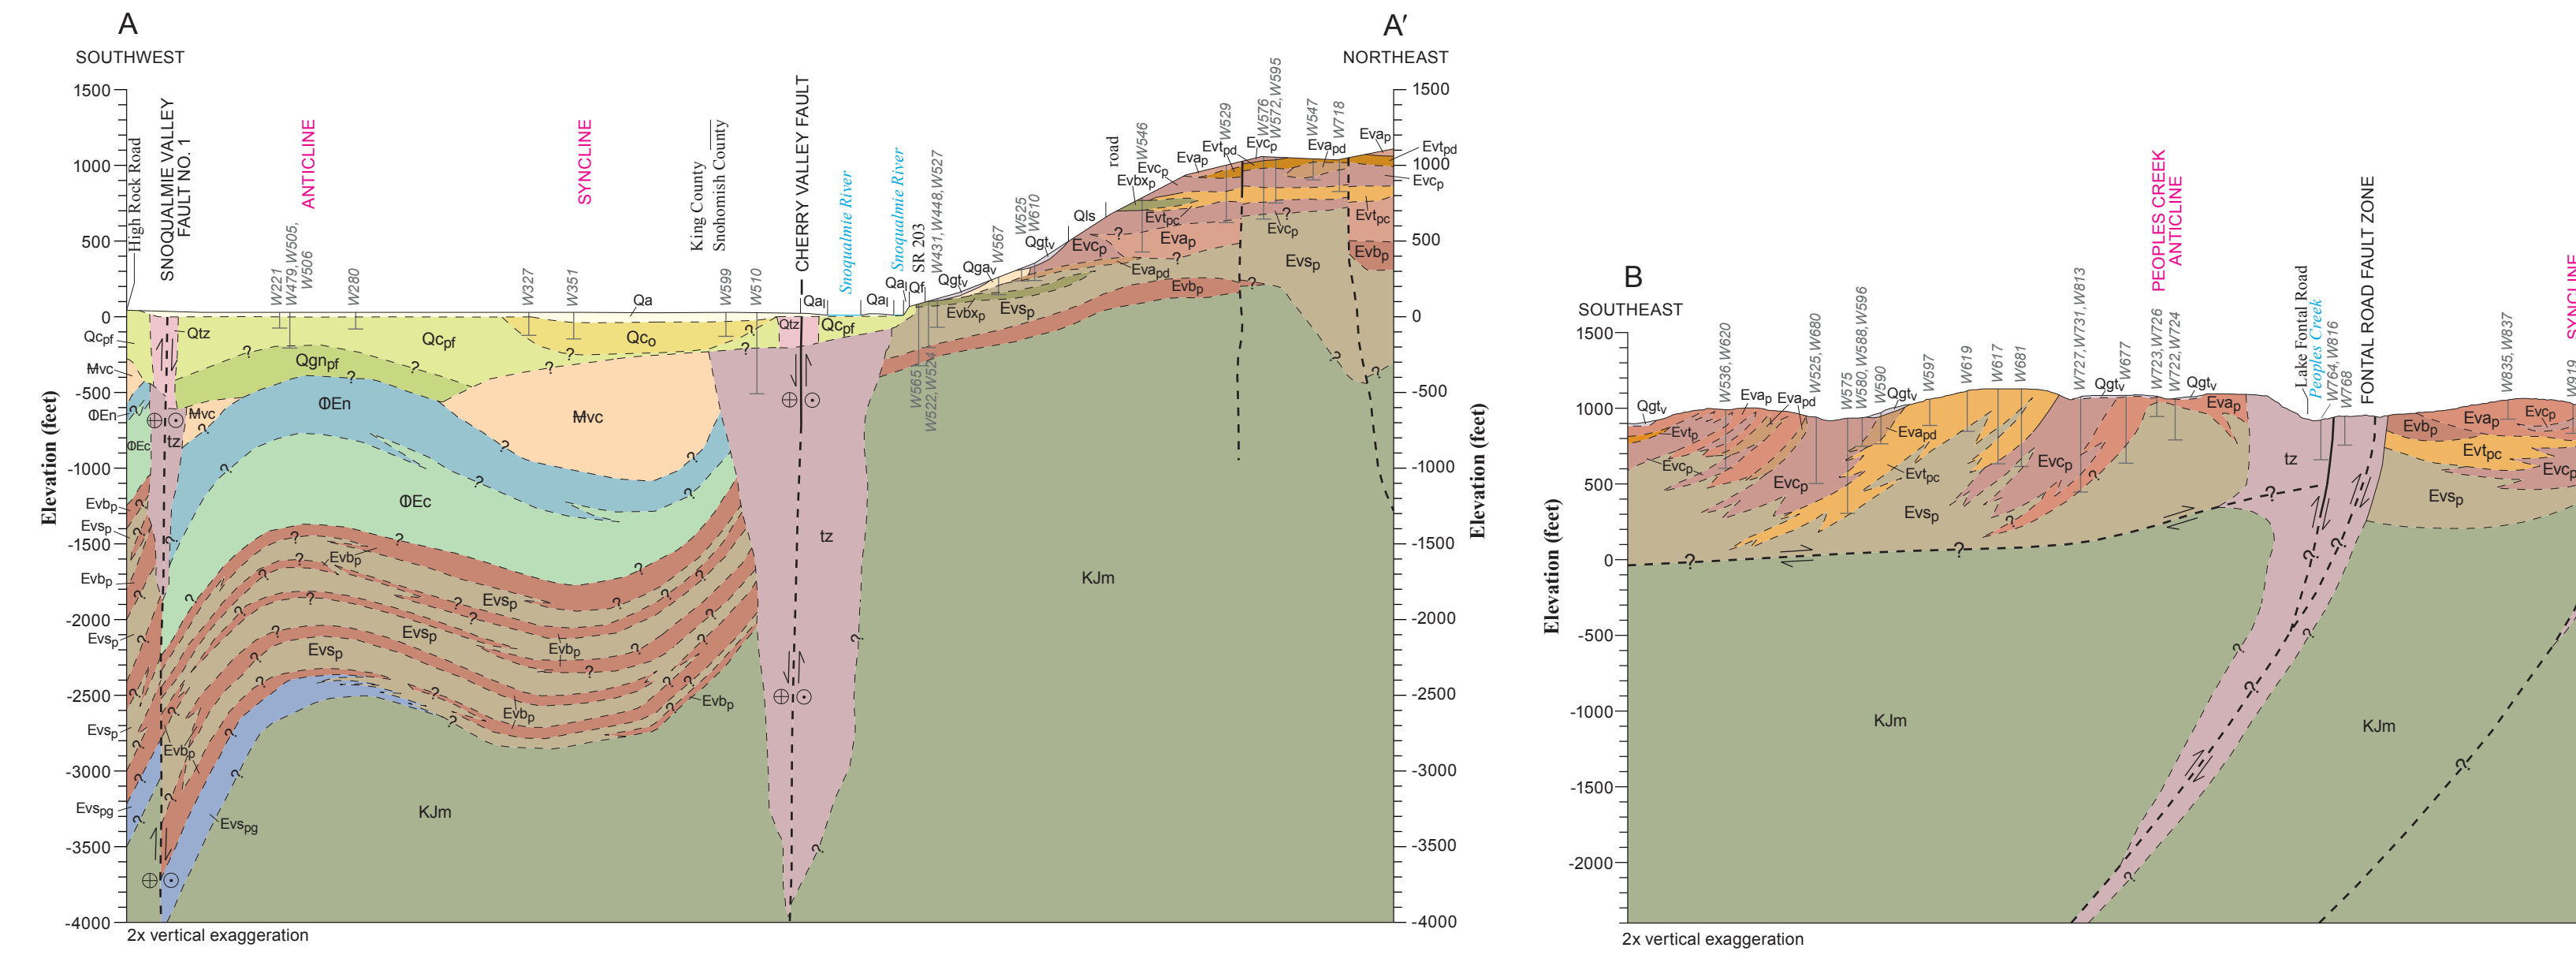

Figure 2. Geophysical cross sections A and B. The geophysical cross sections coincide with lithologic cross sections A and B on the geologic map and match predicted gravity and aeromagnetic anomalies from the cross sections to data from the region (2x vertical exaggeration). Aeromagnetic data sampling distance is on the same order of magnitude as the flightline spacing. Gravity stations shown are within 1.5 km of the line. The model is assumed to extend to infinity in both directions perpendicular to the profile. The blue triangles in the lower panel indicate the height of the flight line above the ground for the aeromagnetic data. $\Delta\rho$ is the density contrast relative to normal crust (2700 kg/m³). χ is magnetic susceptibility in SI units multiplied by 1000. Datum for model A-A' is off the eastern end of the line; appropriate modeling of anomalies required placement of the cross section within a larger regional model (Dragovich and others, 2011). Solid lines show fault locations that are well controlled by the geophysical data. Dashed lines show fault locations that are controlled by geologic mapping at the surface, but are less certain at depth. Percentage of basaltic flows depicted in the volcanic rocks of Mount Persis is directly related to relative changes in magnetism of this unit across the profile. For more information, see Dragovich and others (2011).

FAULT MOVEMENT SYMBOLS IN CROSS SECTIONS

- Relative dip-slip movement
- Movement toward the viewer
- Movement away from the viewer

Some surficial geologic units are too thin to show as polygons at the scale of the cross sections. The extent of these units is shown by short vertical lines that extend upward from the last surface. The geologic unit symbol is placed between the vertical lines so, if space is limited, leading into the space between the vertical lines.
