## INTRODUCTION

On June $30^{\text {th }}, 2022$, NV5 was contracted by the Washington DNR to collect 4-band imagery for the Puget Sound located in northwestern Washington. This report accompanies the delivered imagery and support files, and documents data acquisition procedures, processing methods, and results of all accuracy assessments. Project acquisition details are shown in Table 1, the project extent can be seen in Figure 1, and a complete list of contracted deliverables provided to the Washington DNR can be found in Table 2.

Table 1: Acquisition dates, acreages, and data types collected for the Kelp and Seagrass photo project

## AcQUISITION

Aerial photo acquisition was a joint effort between Geoterra and Peregrine Aerial Surveys, in coordination with NV5. The acquisition teams targeted sun angles between $25^{\circ}$ and $45^{\circ}$, low tides, calm sea states and cloud free conditions. In some instances, targeted environmental condition requirements were relaxed with client approval to ensure completion of the project within the necessary time window. Figure 2 displays photo acquisition flightlines by date.

Figure 2: Acquisition Overview Map for the Kelp and Seagrass photo survey.

## Digital Imagery

The aerial imagery acquisition was a joint effort between Geoterra and Peregrine Aerial Surveys. Geoterra deployed an UltraCam Falcon Prime and UltraCam Falcon Mark 2 (identical interior orientations), manufactured by Vexcel. Peregrine utilized a DMC III camera manufactured by Leica, camera specifications can be found in Table 3 and Table 4. The systems were gyro-stabilized and simultaneously collected panchromatic and multispectral (RGB, NIR) imagery.

Table 3: UltraCam Falcon Camera manufacturer's specifications

| UltraCam Falcon Prime and Mark II |  |
| ---: | :---: |
| Focal Length | 100.5 mm |
| Data Format | RGB NIR |
| Pixel Size | $6.0 \mu \mathrm{~m}$ |
| Image Size | $17,310 \times 11,310$ pixels |
| Frame Rate | 2.0 seconds |
| FOV | $55 \times 37$ degrees |

Table 4: DMC III Camera manufacturer's specifications

| DMC III |  |
| ---: | :---: |
| Focal Length | 92 mm |
| Data Format | RGB NIR |
| Pixel Size | $3.9 \mu \mathrm{~m}$ |
| Image Size | $25,728 \times 14,592$ pixels |
| Frame Rate | 2.0 seconds |
| FOV | $57 \times 34$ degrees |

For the Puget Sound Kelp and Seagrass study area, images were collected in 4 spectral bands (red, green, blue, and NIR) with $80 \%$ along track overlap and $40 \%$ sidelap between frames. The acquisition flight parameters were designed to yield a native pixel resolution of $\leq 6$ inches ( 15 cm ). Orthophoto specifications particular to the Kelp and Seagrass photo project are in Table 5.

Table 5: Project-specific orthophoto specifications

| Digital Orthophotography Specifications |  |
| ---: | :---: |
| Equipment | UltraCam Falcon, UltraCam M2, |
| Spectral Bands | Red, Green, Blue, NIR |
| Ground Sampling Distance (GSD) | $\leq 0.5 \mathrm{ft}$ |
| Along Track Overlap | $\geq 80 \%$ |
| Cross Track Overlap | $\geq 40 \%$ |
| Flight Altitude (AGL) | Variable by sensor |
| GPS PDOP | $\leq 3.0$ |
| GPS Satellite Constellation | $\geq 6$ |
| Image | 8-bit GeoTiff |

## Ground Survey

## Monumentation

Monument locations were selected with consideration for client preference, satellite visibility, field crew safety, and optimal location for GSP coverage. The survey monuments listed in Table 6 provided redundant control $(1 \mathrm{~Hz})$ within 20 nautical miles of the NV5 ground survey. Each monument had two separate occupations with different heights of instrument (HI) using Trimble R7's (Zephyr Geodetic Model 2 RoHS antenna). Monument coordinates are presented in Table 6 and shown in Figure 3.

Table 6: Monuments used to support the Kelp and Seagrass ground survey. Coordinates are on NAD83 (HARN) datum

## Air Targets

Ground survey data were collected by NV5 Geospatial to adjust aircraft positional and attitude data and to perform an accuracy assessment of final orthophoto products. NV5 Geospatial collected hard surface air targets typically on high visibility road markings or painted chevrons. High contrast road markings typically consisted of stop bars, turn arrows or cement corners. Air target points were surveyed throughout the Kelp and Seagrass study area, prior to imagery acquisition, using fast static or RTK techniques (Figure 3). Air target point data (Point ID, Easting, Northing, Orthometric Elevation) were provided to WADNR in the flight data geodatabase (Flight_Index.gdb) within the GIS Data folder of each AOI.

Figure 3: Location map of ground survey data collected for the Kelp and Seagrass photo project

## Processing

## Digital Imagery

The collected digital photographs went through multiple processing steps to create final orthophoto products. Initially, images were corrected for geometric distortion to yield level02 image files. Next, images were color balanced and levels were adjusted to exploit the full 14bit histogram and finally output as level03 pan-sharpened 8bit TIFF images. Photo position and orientation were calculated by linking the time of image capture to the smoothed best estimate of trajectory (SBET). Within Inpho's Match AT softcopy photogrammetric software, analytical aerial triangulation was performed using ground control, automatically generated tie points, and camera calibration information.

Adjusted images were orthorectified using the best publicly available DEM to remove displacement effects from topographic relief inherent in the imagery. The resulting images were mosaicked within Inpho's Ortho Vista blending seams and applying automated project color-balancing. The final mosaics were inspected and edited for seam cutlines across above ground features such as buildings and other man-made features. Special care was taken to use glare free imagery in the final mosaic. The processing workflow for orthophotos is summarized in Table 7.

Table 7: Orthophoto processing workflow

## Orthophoto Processing Step

Software Used

Resolve GPS kinematic corrections for the aircraft position data using kinematic aircraft GPS (collected at 2 Hz ), onboard IMU (collected at 200 Hz ) and PPP data

Develop a smooth best estimate trajectory (SBET) file that blends post-processed aircraft position with attitude data. Sensor heading, position, and attitude are calculated throughout the survey.

Create an exterior orientation file (EO) for each photo image with omega, phi, and kappa.
Convert Level 00 raw imagery data into geometrically corrected Level 02 image files.
Apply radiometric adjustments to Level 02 image files to create Level 03 Pan-sharpened TIFFs.
Apply EO and camera calibration parameters to photos; perform aerial triangulation using automatically generated tie points and ground control processed on project datum Import DEM and generate individual ortho frames.

Mosaic orthorectified imagery, blending seams between individual photos and correcting for radiometric differences between them.

Review seamlines and edit to make sure most nadir part of each image is used and that water glare is reduced or eliminated and seams don't cut through buildings or other manmade features.

## Accuracy Assessment

## Orthophoto Absolute Accuracy

Image accuracy was assessed using air target points, collected by NV5, which were used in the aerial triangulation procedure as control points. These points were found in the final adjusted orthophoto mosaics and the displacement was recorded for further statistical analysis. This methodology was applied to all air targets which intersected each AOI boundary. Note that some air targets fell outside the AOI boundaries but within the footprint of the full aerial imagery acquisition; for example there were eleven air target points surveyed for Tacoma Narrows but all were outside the AOI boundary thus none could be used for an absolute accuracy assessment.

Image orthorectification was performed using the best publicly available DEM, the quality of the DEM used for this process directly effects horizontal accuracy of the final orthophoto products such that erroneous elevations due to temporal differences, DEM survey methodology or coarse DEM resolution can cause offsets in the resulting orthophotos. In some areas of the Kelp and Seagrass photo project offsets were observed, primarily along the inland areas of the shoreline. So while control point residuals in the aerial triangulation report (provided below) are within the accuracy specifications for the project the DEM contributed to horizontal offsets which in some cases fell outside of spec.

Accuracy reporting for both ASPRS guidelines and the National Standard for Spatial Data Accuracy (NSSDA) require at least twenty independent check points per aerial triangulation block for validation, in the case of the Kelp and Seagrass photo project all air targets were used as control points (no independent check points were withheld) in the aerial triangulation procedure due to the limited amount of control available. Table 8, Table 9 and Table 10 present the summary photo accuracy statistics for control points in all AOIs.

## Analytical Aerial Triangulation Report

## Overview

Aerial triangulation was performed in nine blocks to support kelp and eel grass mapping of the Puget Sound and surrounding areas. The nine blocks consisted of 156 flight lines flown at a scale of 1:1,200 between July $25^{\text {th }}$ and October $12^{\text {th }}, 2022$. Block adjustments were made to ground control established by NV5 referencing NAD83(HARN) horizontal datum and NAVD 1988 vertical datum (Geoid12b). Digital imagery along with ground control and camera calibration data were used as input to Inpho's Match AT softcopy photogrammetry program. Of the 91 total surveyed air target points all were used for aerial triangulation and zero were withheld from the block adjustment as independent check points.

## Admiralty Inlet

Air target points used in the aerial triangulation adjustment are listed with their location in Table 11, and RMSE values can be found in Table 12.

Table 11: Location of air target points used as control for aerial triangulation adjustment

## San Juan

Air target points used in the aerial triangulation adjustment are listed with their location in Table 19, and RMSE values can be found in Table 20. During processing the aerial triangulation staff designated four points as anomalies, these points are identified in Table 21 and were removed from further processing.

## Glossary

1-sigma $(\sigma)$ Absolute Deviation: Value for which the data are within one standard deviation (approximately $68^{\text {th }}$ percentile) of a normally distributed data set.
1.96-sigma ( $\sigma$ ) Absolute Deviation: Value for which the data are within two standard deviations (approximately $95^{\text {th }}$ percentile) of a normally distributed data set.
Accuracy: The statistical comparison between known points (air target points) and the same point found in photo mosaics. Typically measured as the standard deviation (sigma $\sigma$ ) and root mean square error (RMSE).

Root Mean Square Error (RMSE): A statistic used to approximate the difference between ground control points and the same point in the orthoimagery. It is calculated by squaring all the values, then taking the average of the squares and taking the square root of the average.

Nadir: A single point or locus of points on the surface of the earth directly below a sensor as it progresses along its flight line.
Overlap: The area shared between images, typically expressed as percent forward and side overlap.
