At 7,980 ft (2,432 m), Mount Olympus is the highest peak in the Olympic Mountains. Reaching this secluded mountain is not easy—you will need to hike 17 miles up the Hoh River valley in Olympic National Park to set foot on its flanks.

The mountain is located at the center of the Olympic Peninsula, known for being the rainiest region in the contiguous 48 states. Due to its prominence, Mount Olympus receives more precipitation than any other mountain on the peninsula—an estimated 261 inches annually (see the precipitation map and profile below)!

The precipitation falls not only as rain, but also as voluminous amounts of snow. This snowfall feeds several large glaciers on Mount Olympus, the most glaciated peak in the Olympic Mountains. Thousands of years ago, during past ice ages, these glaciers were much larger than they are today. The ice-age glaciers carved out the great rainforest valleys of the Olympic Peninsula. As the climate warmed over the last century, the glaciers of Mount Olympus and the Olympic Mountains retreated significantly or to their current extent. Find the Blue Glacier on the map to compare its present-day extent to that of 1899.
